## **Chapter 5. South Coast Hydrologic Region**

The South Coast Hydrologic Regional Profile may surprise some readers of past State Water Plans. Water wholesalers and retailers, groundwater agencies, and watershed planners and managers in the region are being increasingly successful in working together to implement a large and diverse array of local water supply and water quality projects, which in turn is making the region more flexible and less dependent on imported water, particularly during dry years.

This Profile, after describing the characteristics of the region, provides examples of the region's challenges, accomplishments, and plans to meet the water needs of the future. There are many more examples than are given here, but it is important to note that today there are many more major players with important roles to play in providing reliable, affordable, high quality water, and the lines between these entities are increasingly blurred.

### Setting

The South Coast Hydrologic Region, located in the southwest portion of the state, is California's most urbanized and populous region. It contains slightly more than half of the State's population (54 percent), but covers only seven percent of the state's total land area. The topography includes a series of nearly flat coastal plains and valleys, many broad but gentle interior valleys, and several mountain ranges of low and moderate elevation.

The region extends about 250 miles along the Pacific coast from the Ventura-Santa Barbara County line in the north to the international border with Mexico in the south (Figure 5-1). The region includes all of Orange County and portions of Ventura, Los Angeles, San Bernardino, Riverside, and San Diego counties.

There are several prominent rivers in the region, the Sespe, Ventura, Santa Clara, Los Angeles, San Gabriel, Santa Ana, San Jacinto, Santa Margarita, San Luis Rey, San Dieguito, Sweetwater, and Otay Rivers. Some segments of these rivers have been extensively lined and in other ways modified for flood control. Natural runoff of the region's streams and rivers averages about 1.2 million acre-feet annually.

#### Climate

The region has a mild, dry subtropical climate where summers are virtually rainless, except in the mountains where late summer thunderstorms sometimes occur. About 75 percent of the region's precipitation falls during the four-month period from December through March. The coastal plains and the interior valleys receive, on average, 12 to 18 inches of annual precipitation, depending on the station, but the climate allows for a much wider variation from year to year. Much of the 20 to 40 inches of annual average precipitation in the higher mountains falls as snow.

## **Population**

The Region's 2000 population was about 18,223,000. The fastest growing portion of the South Coast Region is that known as the Inland Empire, which includes the inland valleys of Riverside and San Bernardino counties. The region contains seven of the State's fastest-growing cities, in terms of percentage change (Temecula, Chula Vista, Irvine, Riverside, Fontana, Rancho Cucamonga, and

Murietta). The City of Los Angeles is the State's biggest city. Its population grew from 3,624,000 in 1990

to 3,802,000 in 2000. The population in San Diego County is concentrated along the coastal terraces and valleys, and south of Camp Pendleton, the U.S. Marine base. The City of San Diego is now America's 6<sup>th</sup> largest city, and California's second, with 1,240,000 persons.

#### **Land Use**

The mild climate and ample expanse of gentle landscapes in the South Coast Region have encouraged a variety of land uses since the first great development boom of the late 1880s. Residential and commercial development, and

In 1994, State Water Resources Control Board adopted Water Right Decision 1631 amending the City of Los Angeles' water rights for diverting water from the Mono Basin. The decision restricts diversions from the basin to increase and maintain Mono Lake's level to 6,391 feet above sea level. During the period of Mono Lake's transition to the 6,391-foot level (estimated to take about 20 years), the maximum amount of water that Los Angeles can divert from the basin is 16 taf/yr. Long-term Los Angeles diversions from the Mono Basin are projected to be about 31 taf/yr after Mono Lake has reached the 6,391-foot level, or one-third of the city's historical diversions from the Mono Basin.

freeways have continued to extend their way onto lands that had long been pastoral, if not agricultural. Irrigated agriculture now occupies only a seventh as much land as urban uses. Environmental water use is primarily limited to relatively small, managed wetland areas, wildlife areas, lakes, and riparian areas.

Although the acreage devoted to its agriculture has continued to decline in recent years, the region still produced crops on about 280,000 acres in 2000, mostly high-value citrus and vegetable crops and assorted nursery products. For example, annual agricultural products in San Diego County are valued at more than \$1.3 billion. The top crop production value is flowers and foliage, and an extensive citrus and avocado-growing area stretches along Interstate 5 for about thirty miles into the county. Nearly all the 36,000 acres of avocados in this hilly area are grown on slopes and irrigated with high-pressure mini-jet sprinklers and precision emitters.

## Water Supply and Use

The region has developed a diverse mix of both local and imported water supply sources. An array of local projects such as water recycling, groundwater storage and conjunctive use, conservation, brackish water desalination, water transfer and storage, and infrastructure enhancements have been developed to complement imported water supplies. The region imports water through the State Water Project (SWP), the Colorado River Aqueduct (CRA), and the Los Angeles Aqueduct (LAA). This diverse mix of sources provides flexibility in managing supplies and resources in wet and dry years.

The Metropolitan Water District of Southern California (MWD) imports an average of 1.22 million acrefeet of water from the SWP and 550,000 acre-feet or more of water from the CRA (depending on the availability of surplus water). MWD wholesales the water to a consortium of 26 cities and water districts that serve 18 million people living in six counties stretching from Ventura to San Diego.

Fifteen percent of the regions water supply is provided by agencies other than MWD. These agencies import water from the SWP or provide local supplies, usually groundwater. Agencies that import SWP water include Castaic Lake Water District, San Bernardino Valley Municipal Water District, Ventura County Flood Control District, San Gorgonio Pass Water Agency, and the San Gabriel Valley Municipal Water District.

The Santa Ana Watershed Project Authority (SAWPA) is a joint powers authority located in the eastern portion of the region. It represents five agencies in the counties of Orange, Riverside, and San Bernardino and covers a watershed area of 2,650 square miles. It provides effective and concerted watershed planning on a regional basis.

Groundwater and groundwater agencies are important to the water supply picture of the region, meeting about 23 percent of water demand in normal years and about 29 percent in drought years. There are 56 groundwater basins in the region. Groundwater storage capacity is known for only 44 of these basins and is estimated to be more than 133 million acre-feet.

Water use efficiency measures, which bring wastewater agencies into partnerships with surface and groundwater managers, will play an increasingly significant role in meeting the region's water needs. It is estimated that, with the inclusion of Orange County Water District's reuse of the Santa Ana River, the region has developed over 500,000 acre-feet of annual recycled water. This is direct consumption use of recycled water that includes irrigation, industrial uses, and artificial groundwater recharge. In addition,

the region uses approximately 100,000 acre-feet per year of desalinated brackish groundwater. The use of recycled water is expected to increase by 400,000 acre-feet per year during the next decade and the use of desalinated groundwater is expected to increase by approximately 150,000 acre-feet per year over the next decade.

West Basin Municipal Water District (WBMWD), the largest water recycler in the region, has developed over 31,000 acre-feet of recycled water. Currently, about 13,700 acre-feet of recycled water It is interesting to note that during the latter stages of the 1987-1992 drought and for several years afterward, water supply deliveries and M&I uses for many retail water districts in the Region were slightly less than in the late 1980s. The City of Los Angeles, exemplifies this trend. For WY 1990, the City used 677.1 taf of water from various supplies. In 1998 and 2000, the totals were 596.7 and 679.5 taf respectively. The increase in water supplies in 2000 was less than one percent over the 1990 quantities despite a net increase in the population served of more than 400,000.

is beneficially reused within the San Diego County Water Authority (SDCWA) service area annually, 94 percent for agriculture, landscape irrigation, and other manufacturing and industrial uses. The remaining 6 percent is recharged into groundwater basins.

Demand-reduction through water conservation is increasing in the region. Some of the increase is due to active programs that encourage installation of ultra-low-flush toilets and other water efficient appliances for residential, industrial, and institutional uses as well as promotion of water efficient landscaping and irrigation. Even greater conservation is achieved through so-called passive conservation brought about by changes in the water code that require manufacturers to offer customers water-saving devices. MWD reports that its members have urban programs that conserve approximately 65,000 acre-feet annually through active programs, but passive conservation makes the actual savings much larger.

Approximately 14 percent of the overall water use in the region is due to agricultural activities. The sources of water supplies for irrigation operations in the region differ throughout the region. Groundwater is the primary source of water supplies for the agricultural activities on the coastal plain of Ventura County. In the middle section, combinations of groundwater and imported water are used. In the southern portion, primarily San Diego County, imported water supplies are used almost exclusively.

MWD initiated several agricultural water conservation and transfer programs, including a program with the Imperial Irrigation District (IID) that conserved 104,049 acre-feet in 2002 and a crop rotation and water supply program with Palo Verde Irrigation District that saved about 186,000 acre-feet of water from 1992 through 1994 (a full-scale program is underway). In addition, SDCWA is in the initial stage of a project with IID that will deliver up to 200,000 acre-feet of conserved water annually to San Diego County.

The following water balance table summarizes the detailed regional water accounting contained in the water portfolio at the end of this regional description. As shown in the table, losses are about the same as precipitation and outflows to the ocean are relatively small. Imports are a large part of the applied water in the region.

### State of the Region

Over the past decade, the region has improved water supply reliability in the face of reduced supplies from the Owens Valley and Mono Basin and uncertainty regarding the amount of imports from the State Water Project and Colorado River. Water agencies have been proactive in continuous planning to manage changing water supply and demand conditions in the region. While dependent on imported water for at least 50 percent of its water supplies, the region's water agencies have compiled a wide array of water management tools and water management and planning practices that bring local water resources on a more equal footing with imported water.

#### Challenges

Like many regions in the state, water quality and water supply challenges are inter-twined. The region must manage for uncertainties caused by population and economic growth. Growth will not only affect demand, but it will add contamination challenges from increases in wastewater discharges and urban runoff, as well as increased demand for water-based recreation. Outside the region, environmental and water quality needs in the Delta, Colorado River, and Owens River/Mono Basin systems affect imported water supply reliability and quality. The region must also assess and plan for impacts of climate variations and global climate change, as well as the cost of replacing aging infrastructure.

Given the size of the region and the diverse sources of water supply, the challenges to the region's water quality are varied. There are no single solutions, and some solutions create additional problems. Supplies such as imported water from the Owens Valley and the Delta may be high in arsenic, organic carbon and/or bromide. Colorado River water is high in total dissolved solids (TDS) and has other problem constituents, such as perchlorate, a component of rocket fuel.

Total dissolved solids concentration affects the feasibility of water recycling and groundwater recharge programs. Because residential use of water increases TDS concentration, water recycled from even moderately high TDS source water can result in unacceptably high TDS concentrations. Groundwater recharge potential may be restricted because the Regional Water Quality Control Board has established TDS requirements for recharge water in some groundwater basins to protect existing basin water quality.

The average TDS concentration of MWD's Colorado River water in 1996 was about 700 mg/L and the average TDS content of MWD's SWP supplies was about 300 mg/L. The City of Los Angeles' water supply from the eastern Sierra Nevada had a significantly lower TDS concentration, typically about 160

mg/L. TDS levels in local groundwater supplies in the South Coast Region vary considerably, ranging from 200 mg/L (Cucamonga Basin near Upland) to more than 1,000 mg/L (Arlington Basin near Corona).

Local sources of salinity also contribute significantly to overall TDS levels. Municipal and industrial use of water adds between 250 and 500 mg/L of TDS to wastewater. Key sources of local salts include water softeners (typically contributing from 5 to 10 percent of the salt load) and industrial processes.

The long-term salt balance of South Coast Region's groundwater basins is an important management concern. Smaller basins like the Arlington and Mission groundwater basins were abandoned as municipal supply because of high salinity levels. These basins have only recently been restored through brackish water desalting projects. Blending SWP and CRA supplies or using the SWP's relatively low TDS supplies for groundwater replenishment has been a goal in some areas. However, some inland agencies that reuse wastewater have salt accumulation problems in their groundwater basins because they lack an ocean outfall or stream discharge. Other inland agencies have established access to a brine line for exporting salt and concentrated wastes to a coastal treatment plant and ocean outfall, while others have not found construction of a brine line to be economical.

Water agencies treat and manage their supplies to meet or exceed all drinking water quality standards required by the state and federal laws. Pending and future EPA and state regulations will undoubtedly raise some of these standards and add new contaminants to the treatment list. Several established and emerging contaminants of direct concern to South Coast Regional water supplies include disinfection byproducts (DBPs), perchlorate, arsenic, NDMA, hexavalent chromium and MTBE.

Disinfection by-products (DBPs) are regulated by the Stage 1 Disinfection/Disinfectant By-Product Rule (D/DBP Rule). The D/DBP Rule balances the need for adequate disinfection to inactivate pathogens with the need to reduce the formation of DBPs that may harmful to human health. Dissolved organic carbon (DOC) and bromide, present in SWP supplies, have forced many South Coast region water utilities to remove the DBP precursors or rely upon alternative secondary disinfectants, such as chloramines, rather than chlorine. Another DBP, bromate, is also of concern in this region when ozone is used to treat water with high levels of bromide, a natural constituent of water from the Delta.

Perchlorate has been identified in groundwater in Los Angeles, San Bernardino, and Riverside counties and in Colorado River water. Perchlorate is an inorganic constituent present in rocket fuel, which is believed to disrupt thyroid gland function in humans. Perchlorate in Colorado River water is largely due to contamination from inactive ammonium perchlorate manufacturing facilities in Nevada. Discovery of perchlorate contamination of wells in the San Gabriel Valley, which put many of these wells out of production, has led to testing of ion exchange technologies for the removal of this constituent.

Arsenic is another contaminant of concern in the South Coast Region, largely but not exclusively to the City of Los Angeles. High concentrations of arsenic present in the LAA supply and local aquifers are due to natural sources. The City of Los Angeles manages arsenic in LAA water through treatment and exchanges with MWD. Ingestion of high concentrations of arsenic in drinking water has been linked to skin disorders, circulatory problems, and increased risk of cancer. Removal of arsenic from supplies currently relies primarily on ion exchange, coagulation/filtration, and reverse osmosis processes. In southern California, water sources with high arsenic levels have also been found in Los Angeles, San Bernardino, and Riverside counties.

Nitrosodimethylamine (NDMA) is associated with the production of rocket fuel, the manufacture of explosives, and in the manufacture of paints and other industrial goods. NDMA is a contaminant of concern because it causes cancer in a variety of laboratory animals and is a probable human carcinogen. Contamination of surface and groundwater supplies from NDMA at missile and other rocket fuel sites has been characterized as a significant concern, particularly for groundwater supplies. NDMA formation during the treatment of wastewater is also a concern to drinking water supplies when wastewater is recharged into aquifers. NDMA is currently treated in drinking water supplies by ultraviolet radiation (UV).

Groundwater contamination by hexavalent chromium in the Los Angeles region and elsewhere has resulted from its use in various industries including aerospace, aircraft manufacturing, and plating. Hexavalent chromium is known to be a carcinogen by inhalation, and carcinogenic effects by ingestion are suspected. Currently, only total chromium is regulated, but California has initiated unregulated contaminant monitoring to determine how widespread hexavalent chromium contamination is in the state. Promising technologies for removing hexavalent chromium include ion exchange, coagulation/filtration, and reverse osmosis, although no technologies have yet been demonstrated on a full-scale basis. In Los Angeles County, Regional Water Quality Control Board staff is overseeing assessment and cleanup of sites impacted by hexavalent chromium at defense-related businesses and manufacturing and other industrial sites.

MTBE and other oxygenates have been added to gasoline in areas with severe air pollution to help gasoline burn more cleanly and comply with federal law. MTBE has caused public concern because it can contaminate groundwater when pipelines, fuel tanks, and other containers or equipment leak, when fuel is spilled, and when unburned fuel is discharged from watercraft. The high mobility and low biodegradability of MTBE presents significant risk to aquifer supplies when MTBE spills or leaks occur. MTBE has been detected in groundwater supplies in Los Angeles, Orange, Riverside, Ventura, and San Diego counties. It has also been detected in imported and local surface water supplies. The health effects of MTBE are uncertain, but MTBE may have potential non-cancer effects or may be a carcinogen at high doses. MTBE can be removed from drinking water supplies by air stripping, granular activated carbon (GAC), or advanced oxidation.

California's use of Colorado River water is being managed to ensure that the region reduces by 2016 the use of this water from a high of 5.3 million acre-feet in previous years to its 4.4 million acre feet annual apportionment. Until 2016, California can receive surplus water from the river depending on the storage level in Lake Mead. The California Colorado River Water Use Plan (the Plan) outlines steps to be taken to reduce the use of Colorado River water. Those steps include a water transfer of conserved water from IID to SDCWA, the lining of earthen canals, water storage and conjunctive use programs, water exchanges, improved reservoir management, salinity control, watershed protection, water reuse, and other measures.

Drought is a constant concern for water agencies in the region. This has led to an emphasis on the development of local supplies. Today, about 50 percent of southern California's demand is being met through such local supplies as water conservation, recycling, and groundwater recovery. The uncertainty caused by scientific findings on climate change also has caused water agencies to question the reliability of imported sources.

Groundwater overdraft is a challenge to the region. Historically, agricultural, industrial, and urban development has led to extraction of increasing amounts of groundwater from many of the region's basins. Over-extraction of groundwater has caused seawater intrusion, contributed to land subsidence, and led to disputes over pumping rights in many of the region's basins.

Local surface water quality is affected by stormwater and urban runoff, which contribute contaminants (including trash) to local creeks and rivers. The presence of contaminants, as well as the presence of inadequately treated wastewater resulting from sanitary sewer overflows, has closed beaches and affected water quality in Santa Monica, Newport, and San Diego bays.

During shipping activities, accidents such as spilling of fuels and sewage may occur, which can also affect water quality, especially at the Long Beach and Los Angeles Harbors and the U. S. Naval Port in San Diego Bay.

### **Accomplishments**

The region has developed a diverse water portfolio that is balanced between local and imported supplies. The primary objectives of the regions water agencies are to provide high quality, reliable, and affordable water. To achieve this balance, the region has constructed additional surface storage capacity and

employed several local resource management strategies including improved conveyance facilities, agricultural and urban water use efficiency, water recycling, groundwater conjunctive, groundwater remediation, brackish water desalination, drinking water treatment, watershed management, and groundwater banking and water transfers from outside the region. These diversified strategies guide the management of available resources in a manner that allows greater flexibility when adapting to water quality or supply challenges.

Diamond Valley Lake was constructed in the late 1990s to better manage water supplies between wet and dry years. The 800,000 acre-foot reservoir, located near Hemet in southwestern Riverside County, nearly doubles the region's existing surface storage capacity and provides increased terminal storage for SWP and Colorado River water supplies. Diamond Valley Lake would provide the MWD service area with a six-month emergency imported supply after an earthquake or other disaster. It would also provide water supply for drought protection and peak summer demands.

The SDCWA finished construction of Olivenhain Reservoir in 2003 and began filling its 24,000 acre-foot capacity with imported water. The reservoir, located just southwest of Escondido in northern San Diego County, will provide water to the San Diego region during an emergency that cuts off normal imported water deliveries. It is the first milestone completed in the SDCWA Emergency Storage Project, which will add 900,100 acre-feet of storage capacity within the county.

The Inland Feeder is a conveyance facility to deliver SWP water made available by enlargement of the East Branch of the California Aqueduct. Upon its completion in 2004, the Inland Feeder will deliver water by gravity to Diamond Valley Lake via 43.7 miles of tunnels and pipeline that start at Devil Canyon and tie into the CRA and Eastside Pipeline. The Inland Feeder will provide system reliability by linking the SWP and Colorado River systems and will improve water quality by allowing greater blending of SWP and Colorado River waters.

An agreement between MWD and San Bernardino Valley Municipal Water District (San Bernardino) allows MWD to purchase additional SWP water for blending with Colorado River water and to store water from San Bernardino's groundwater basin, which helps resolve long-standing groundwater issues. The San Gorgonio Pass Water Agency recently extended the pipeline east from Mentone bringing SWP water to Beaumont.

On October 10, 2003, representatives from MWD, IID, and Coachella Valley Water District (CVWD) signed the Quantification Settlement Agreement (QSA) and several other agreements that will execute several key components of the Colorado River Water Use Plan including establishing water budgets from IID and CVWD and making water transfers viable. The QSA includes a water transfer from IID to SDCWA, which began in 2003 and eventually will provide 200,000 acre-feet per year to San Diego County. The transfer will help increase water supply reliability for the South Coast Region.

State agencies, including the Department of Water Resources (DWR), the State Water Resources Control Board (SWRCB), and the California Bay-Delta Authority (CBDA), and the Federal Bureau of Reclamation are making major statewide investments in urban and agricultural water conservation programs, which regional and local agencies leverage with their own investments to reduce demand. As discussed above, additional demand reduction comes from passive conservation achieved through changes in manufacturing codes.

An example of this regional leveraging is MWD's conservation program with its member agencies. Since 1992 Metropolitan has invested more than \$191 million in conservation programs and related activities. In 2003, MWD implemented a new rate structure that includes a funding source dedicated to conservation, recycling, groundwater recovery, and other local projects. The backbone of MWD's conservation program is the Conservation Credits Program, initiated in 1988, that contributes \$154 per acre-foot of water conserved to assist member agencies in pursuing conservation opportunities. In tandem to these urban conservation efforts, MWD has an agricultural water savings program that began in 1990 with IID. To date, MWD has invested more than \$193 million to construct, operate, and maintain projects with IID that will conserve more than 100,000 acre-feet of agricultural water every year to transfer to MWD. In 2003, water savings were 105,130 acre-feet. This agreement is for a minimum of 43 years.

A 35-year agreement for a land management, crop rotation and water supply program is in place with the Palo Verde Irrigation District and MWD. Palo Verde farmers will stop irrigating between 7 to 29 percent

of their land, on a rotating basis, securing about 8 to 36 billion gallons of water each year for use in southern California. MWD will provide an estimated \$6 million to local community improvement programs to counter potential negative economic impacts to the Palo Verde community.

Over \$440 million, primarily from State Propositions 13 and 50 and federal Title XVI grants, have been invested in water recycling programs in the region, resulting in over 500,000 acre-feet of water available per year, including Orange County Water District's (OCWD) current reuse of Santa Ana River water. The growth in recycled water will be about 400,000 acre feet over the next decade.

The OCWD's new Groundwater Replenishment (GWR) System is designed to increase current water reuse by taking treated sewer water that is currently being released into the ocean and purifying it through microfiltration, reverse osmosis, and ultraviolet light with hydrogen peroxide advanced oxidation treatment. The purified water will be injected into a seawater barrier and pumped to percolation ponds to seep into deep aquifers and blend with Orange County's other sources of groundwater.

The development of groundwater storage and conjunctive use programs has improved the region's water supply reliability and overall water quality. A 2000 study by the Association of Groundwater Agencies indicates that existing conjunctive use programs in the region provide an estimated 2.5 million acre-feet of water per year, which is a small fraction of the region's conjunctive use potential. It is estimated that over 21.5 million acre-feet of additional water could be stored and used in southern California groundwater basins with the resolution of institutional, water quality, and other issues. State agencies have supported the development of 34 groundwater management and storage projects in the region.

As a result of MWD's replenishment services pricing program, local agencies are implementing conjunctive use programs. They are storing imported water in groundwater basins and increasing their groundwater use during the summer and during drought years. It is estimated that an average of 100 thousand acre-feet per year of groundwater supply is now produced as a result of MWD's discount pricing deliveries. MWD has identified the potential for 200 thousand acre-feet of additional groundwater production during drought years. To accomplish this additional drought year production, about 600 thousand acre-feet of dedicated storage capacity within the local basins may be required.

An example of such a conjunctive use program is the Las Posas Basin Aquifer Storage and Recovery Project. The Calleguas Municipal Water District, in cooperation with MWD, has initiated a conjunctive use program in the Las Posas Groundwater Basin of Ventura County. The project is designed to store a maximum of 210,000 acre-feet of SWP water supplies that can be used during water supply shortages. The project will be phased into operation with full operation anticipated by 2010. To date, 18 wells have been constructed and approximately 50,000 acre-feet of water is in storage.

More recent groundwater storage agreements allow additional storage in wet years. Groundwater agreements to be implemented in the region will put more than 53 billion gallons of water into storage in Orange County, the west San Gabriel Valley and the Inland Empire. MWD reached agreements the Kern-Delta Water District, the Mojave Water Agency, and the North Kern Water Storage District, outside the region, where it also

participates in the Semitropic Water Banking and Exchange Program in Kern County, the Arvin-Edison Water Storage Program in Kern County, and the Kern-Delta Storage Program. Castaic Lake Water Agency entered into a short-term groundwater banking arrangement with Kern County.

Groundwater quality issues are being addressed in the region. In the San Gabriel Valley, the Main San Gabriel Basin Watermaster, San Gabriel Basin Water Quality Authority, Upper San Gabriel Valley Municipal Water District, and a number of water suppliers have actively pursued technical remedies for the groundwater quality problems described earlier. Several treatment facilities for the VOCs were first constructed in the 1990s. As of June 2002, 18 treatment facilities are operational. Groundwater supplies with high nitrate levels are either blended with other supplies or not used at all. Similar cleanup efforts are being pursued in the San Fernando Basin by LADWP and the Upper Los Angeles River Basin Watermaster.

Brackish groundwater desalting delivers about 100,000 acre-feet of water today and will increase to approximately 250,000 acre-feet during the next decade.

Several groundwater desalting plants are currently operated by the SAWPA, Chino Basin Desalting Authority, City of Corona, Eastern Municipal Water District's, Irvine Ranch Water District, the City of Oceanside, West Basin MWD, and the Sweetwater Authority. Proposition 13 water bond funding is being utilized to expand desalting capacity in the region.

SAWPA operates a brine disposal line, which facilitates disposal of waste brine from regional desalting plants and operates the Arlington Desalter. SAWPA has been particularly successful in recent years in assisting its member agencies in implementing several new water resources projects that enhance groundwater recovery, groundwater storage, water quality improvement and water recycling through the use of Proposition 13 Water Bond funding. Approximately 20 potential groundwater recovery projects were evaluated with a net yield of 95,000 acre-feet per year.

The Port Hueneme Water Agency was formed to develop and operate a brackish water desalting demonstration facility for its member agencies in western Ventura County. Its goals are to improve the quality and reliability of local groundwater supplies and decrease seawater intrusion in the Oxnard Plain. The facility will provide a full-scale demonstration of side-by-side operation of three brackish water desalting technologies: reverse osmosis, nanofiltration, and electrodialysis reversal. The feasibility of using desalting concentrate for wetlands enhancement is also being studied.

Increasingly, the region's water wholesalers, such as Castaic Lake Water Agency, San Bernardino Valley Metropolitan Water District, Mojave Water Agency (MWA), MWD, and San Diego County Water Authority are acquiring part of their future supplies from water marketing or exchange arrangements, using the CRA and California Aqueduct to convey the water.

An agreement in late 2003 between MWA and MWD calls for the exchange of 75,000 acre-feet of SWP flow from the California Aqueduct. Under the accord, MWA received about 23,000 acre-feet of MWD's state-authorized flow via the aqueduct at the end of 2003. Additional flow through this agreement will depend on the amount of rain or snowfall available to the SWP. Water will be stored in the high desert's underground aquifers to help replenish the water table, prevent well-deepening by residents, and meet future needs.

In 2003, the SDCWA and IID consummated the largest water transfer in the history of the United States. This transfer, which eventually will move 200,000 acre-feet of conserved water by farmers in the Imperial Valley to San Diego County, has helped reduce SDCWA's dependence on MWD and diversified its sources of imported water. The initial term of the agreement is for 45 years; a 30-year extension is possible with the mutual consent of both parties. In addition, SDCWA will gain an additional 77,000 acre-feet of water per year through projects it will undertake to line the All-American and Coachella canals to stop water loses that occur because of seepage. This program has a 110-year term.

The South Coast region has placed an increased emphasis on improving watershed management and protection. Local, state, and federal agencies and nonprofit organizations have invested in several management efforts, including watershed education, monitoring, and wetlands management and protection. There are over 40 entities that are generating new partnerships and coalitions among various stakeholders in attempts to integrate elements of flood hazard mitigation, groundwater and stormwater conservation, management of the quality of stormwater runoff, along with other natural resources, to better manage sources. Following are examples of the region's watershed programs:

- SAWPA, the largest watershed organizations, is established to protect and enhance the quality and supply of the watershed and protect the environment by implementation of its watershed plan.
- Under the guidance of the Los Angeles County Department of Public Works, watershed
  management plans are being developed for five coastal watersheds within Los Angeles County.
  Eleven watershed and sub-watershed plans have been completed with eight pending or proposed

- plans underway, making Los Angeles County the most productive county in the state in terms of watershed planning.
- The Hemet/San Jacinto Multipurpose Constructed Wetlands is a collaborative project between the US Bureau of Reclamation and Eastern Municipal Water District. The Wetlands is nearly 60 acres in size and consists of five interconnected marshes. It provides nitrogen removal of secondarytreatment recycled water and habitat for migratory waterfowl, shore birds, and raptors along the Pacific Flyway.
- The San Diego Creek Watershed is operated by the Irvine Ranch Water District. The watershed program helps sustain a restored marsh and treats contaminated urban runoff water from San Diego Creek before it enters into Newport Bay in Orange County.
- The Orange County Water District (OCWD) operates the Prado Basin Wetland in Riverside County. In cooperation with the United States Army Corps of Engineers and the United States Fish and Wildlife Service, OCWD operates 465 acres of constructed freshwater wetlands to reduce the nitrogen concentration of river water.

### Looking to the Future

The region's water agencies generally have solid plans for adapting to changing conditions and meeting future water needs. For example, the 2003 Report on Metropolitan's Water Supplies states, "Metropolitan has a comprehensive supply plan to provide sufficient supplemental water supplies and to provide a prudent supply reserve over the next 20 years and beyond." The Santa Ana Watershed Program (SAWPA) has begun a 10-year integrated program to help, among other things, drought-proof the watershed so that it can roll off imported water for up to three years during drought years. Water agencies in the Santa Clarita Valley are engaged in integrated urban water management planning, collaborative data collection, and a new groundwater plan. These and other ongoing planning programs are important to manage changing conditions facing the

#### **Integrated Resource Planning**

MWD adopted its Integrated Resource Plan (IRP) in 1996 and recently has updated that plan with the Draft 2004 IRP. The Draft 2004 IRP accomplishes the three objectives of reviewing goals and achievements of the 1996 IRP, identifying changed conditions for water resource development, and updating the resource targets through 2025.

SAWPA recently completed its 2002 Integrated Water Resource Plan. It provides information on water demand and supply planning, water resource plans from member agencies, balancing and integrating available resources, and identifying regional problems and issues and potential long-term solutions.

region. Water conservation programs, water recycling, and groundwater recovery, as well as water marketing and other water supply augmentation responses are being examined and implemented.

California's Colorado River Water Use Plan describes how California will reduce its use of river water over time to its allotted 4.4 million acre-feet per year. The first phase of the plan, extending from the present to 2010 or 2015, consists of those actions that are now in some stage of planning and implementation. These programs are intended to reduce California's annual use of Colorado River water to 4.6-4.7 million acre-feet. The second phase consists of actions that have not yet been formulated and quantified. Examples of phase one actions are the San Diego County Water Authority-Imperial Irrigation District transfer of Colorado River water; the lining of parts of the All-American Canal (23 miles), which will conserve 67,000 acre-feet of water each year that will be available for transfer, and the All-American Canal and groundwater banking projects associated with surplus Colorado River water. An example of

potential phase two actions is desalting water in Salton Sea tributaries and conveying the treated water to the South Coast Region.

MWD will continue its replenishment services pricing program to encourage local agencies to store imported water in groundwater basins for use during the summer and during drought years. In addition, local agencies in the region are now planning to use water transfers for part of their base supplies, a change from past years when marketing arrangements were viewed as primarily for drought year supplies.

Ocean water desalination is sometimes described as the ultimate solution to Southern California's water supply shortfall. While it has become a more feasible source of supply due to technical advances, its development is restrained by high costs, environmental impacts of brine disposal, and plant siting considerations. State agencies have provided funding for the Desalination Research and Innovation Partnership, which furthered the development of advance reverse osmosis membranes.

MWD and five of its member agencies have planned the development of 126,000 acre-feet of desalinated ocean water. Those member agencies include LADWP, Long Beach Water Department, Municipal Water District of Orange County, West Basin Municipal Water District, and SDCWA. The SDCWA expects desalted ocean water to meet between 6 and 15 percent of the region's needs by 2020 and is conducting an environmental review for building an ocean water desalination facility on the Encina Power Plant property in Carlsbad. SDCWA also is carrying out feasibility studies of desalination facilities at Camp Pendleton and in the southern county. All three site are located on the coast.

Another future water supply option is management of the San Bernardino Basin as a groundwater storage facility. The Basin has a capacity of about 5.5 million acre- feet. Pursuant to the January 1969 settlement for Western Municipal Water District *et al.* vs. East San Bernardino Valley Municipal Water District *et al.* Superior Court Riverside County Case number 78426, the Western-San Bernardino Watermaster determined that the safe yield of the San Bernardino Basin Area is about 232,000 acre-feet per year. SBVMWD has been working with USGS for many years to develop a groundwater model that will enable the agency to enhance the safe yield of the basin.

Orange County Water District and Orange County Sanitation District are sponsoring the Groundwater Replenishment System. The project will take highly treated wastewater and treat it beyond drinking water standards for groundwater recharge and injection into the seawater barriers along the coast. This project will provide a second and reliable source of water to recharge the Orange County Basin; protect the Basin from further water quality degradation brought on by sea water intrusion; and augment the existing recycled water supply for irrigation and industrial uses.

Existing flood control reservoirs are now being evaluated for their potential to provide some water supply benefits through the modification of the operation of the facilities to enhance groundwater recharge and provide limited year-round storage. The San Bernardino Valley Municipal Water District, for example, has applied to the SWRCB for authorization to store stormwater from the Santa Ana River in a reservoir that could be created by Seven Oaks Dam. LACDPW is completing a study, in cooperation with the Army Corps of Engineers, to reauthorize four Corps flood control facilities in Los Angeles County for the purpose of capturing and safely storing stormwater and then slowly releasing the water to downstream groundwater recharge facilities after storm events.

The Water Augmentation Study is a long-term research project, led by the Los Angeles and San Gabriel Rivers Watershed Council and supported financially by its partners, the Bureau of Reclamation, MWD, LACDPW, LA RWQCB, WRD of Southern California, LADWP, Los Angeles City Sanitation, and the City of Santa Monica. The purpose of the study is to explore the potential for increasing local water supplies and reducing urban runoff pollution by increasing infiltration of stormwater runoff upstream. The project was initiated in January 2000 to assess the impact of runoff-transported pollutants on rivers, coastal water, and beaches; the viability of adding these stormwater resources to local water supplies, and the challenge of capturing stormwater for infiltration, in terms of both groundwater quality and quantity.

Two Examples of ongoing ecosystem restoration projects:

The Matilija Dam Ecosystem Restoration Feasibility Study is evaluating alternatives and will recommend a preferred method for removing the 160-foot high dam, including stored sediment, to restore the Ventura River ecosystem.

The Santa Ana River Trail and Parkway Project includes planning of recreational uses that showcase the river and provide a place for people to enjoy this important resource.

The Mojave Water Agency (MWA) has embarked on a Regional Water Management Plan (RWMP) Update that will provide a regional roadmap for managing water resources and ensuring a reliable water supply for the future of the MWA desert region. While MWA relies predominately on groundwater, it also receives water from the California Aqueduct as one of 29 SWP Contractors. The RWMP Update will address population growth, water demand projections, stakeholder needs and issues, facilities needed to replenish groundwater supplies, and revenue alternatives.

In 2000, DWR, in cooperation with the U. S. Bureau of Reclamation and 10 Southern California water and wastewater agencies, undertook the Southern California Water Recycling Projects Initiative to continue the work begun during the Southern California Comprehensive Water Reclamation and Reuse Study (SCCWRRS). The Initiative is a multi-year planning study that evaluates the feasibility of a regional water-recycling plan and assists local water and wastewater agencies in final planning and environmental documentation leading to implementation of projects identified in the SCCWRRS. The Initiative is funded on a 50/50 percent cost-sharing basis among the 12 agencies. The Initiative identified short-term projects that could add approximately 378,000 acre-feet of recycled water for regional use. The fifteen short-term projects identified were as follows: Calleguas, East San Gabriel, West Basin, Central Basin, Noth Orange County, Central Orange County, Upper Oso, San Juan, Encina, San Pasqual Valley, North City, South Bay, Chino Basin, San Bernardino, and Eastern.

As part of a regional strategy to improve water supply reliability, several agreements with water districts in the Central Valley are providing groundwater storage for the South Coast Region:

- Semitropic Water Banking and Exchange Program. This program allows storage of up to 350,000 acre-feet in the groundwater basin underlying the Semitropic Water Storage District in Kern County.
- Arvin-Edison Water Storage Program. MWD and the Arvin-Edison Water Storage District have developed a program that allows Metropolitan to store water in the groundwater basin in the Water Storage District's service area in Kern County. Over the next 25 to 30 years, this groundwater storage program will provide average dry-year withdrawals of about 70,000 acre-feet annually.

 Kern-Delta Storage Program. This 25-year program will allow storage of up to 250,000 acre-feet of available State Water Project supplies.

Other potential management strategies includes interstate groundwater banking in Arizona, drought year land fallowing programs, lining parts of the All-American and Coachella Canals, and agricultural water conservation beyond EWMP implementation. In addition, South Coast Region water agencies are storing discounted winter-imported water in groundwater basins and increasing their groundwater use during the summer and during drought years.

The Calleguas Municipal Water District operates a conjunctive use program in the Las Posas Groundwater Basin of Ventura County. Identified as the Las Posas Basin Aquifer Storage and Recovery Project, it is designed to store a maximum of 300,000 acre-feet of water supplies that can be used during short-term and long-term water supply shortages. The project calls for the construction of 30 dual-purpose wells that will be used for both injection and production. Pipelines will be constructed to connect the wells with CMWD facilities as far away as the Cities of Simi Valley and Thousand Oaks. The source of water supplies would be the State Water Project. The Project will be phased into operation with full operation anticipated by 2010. To date, 18 wells have been constructed and approximately 50,000 acrefeet of water is in storage.

To improve the reliability of its potable water supplies during droughts, the Western Municipal Water District is moving forward with plans to operate a conjunctive use program in groundwater basins in western San Bernardino and Riverside Counties. The project, the Riverside-Corona Feeder, calls for the recharge of water supplies during above-average precipitation years into the groundwater basins in San Bernardino Valley and pumping those supplies during drought years. Sources of water for the recharging operations would be local surface runoff, including releases from the Seven Oaks Reservoir near the community of Mentone in San Bernardino County and the State Water Project. Recipients of the stored groundwater supplies are Cities of Corona and Riverside and the Elsinore Valley Water District. When complete, 20 wells and 28 miles of pipeline would have been constructed. Approximately 40,000 acrefeet of groundwater supplies could be moved by the project.

Most of the projects described above are designed to improve water quality as the way to increase water supply. These include watershed activities, such as the Water Augmentation Study, groundwater desalination, use of highly treated recycled water by the Orange County Water District, reduction of sewage spills and stormwater runoff through water conservation, and surface and groundwater storage project that implement blending and treatment strategies to reduce disinfection byproducts and other regulated and unregulated contaminants in treated drinking water supplies.

In addition, MWD has committed to retrofitting all five of its water treatment plants to use ozone; adding fluoride to treated drinking water supplies; implementing a recreation policy for Diamond Valley Lake that protects drinking water quality; supporting salinity reduction projects in the region; and outside the region helping preserve and enhance the Sacramento River Watershed, which is an important source of water for the State Water Project system.

### **Key Elements of Colorado River Quantification Settlement Agreement**

The Colorado River Quantification Settlement Agreement will have the following effects:

- Have California adopt specific, incremental steps to gradually reduce its use of Colorado River water over the next 14 years to its basic annual allotment of 4.4 million acre feet.
- Provide Arizona, Colorado, Nevada, New Mexico, Utah and Wyoming with certainty on use of the river, allowing them to take their full allotments to meet future water needs.
- Restore California's and Nevada's privileges to draw extra water from the Colorado River to meet the needs of urban Los Angeles and Las Vegas.
- Transfer as much as 30 million acre-feet of water from farms to cities in Southern California over the life of the agreement.
- Settle a lawsuit between the Imperial Irrigation District and the U.S. Department of Interior (DOI), in which DOI had accused the farming region of wasting water.
- Launch an ambitious plan to reduce Salton Sea salinity, which receives agricultural waste water from Imperial Valley farms, and enhance the Sea and adjacent wetlands for migratory birds.
- Provide for \$163 million to offset the environmental impacts of the water transfer in the arid Imperial Valley and help fund the cost of restoring the Salton Sea.
- Fund a \$200 million project to line the earthen All-American Canal, which delivers Colorado River
  water to the Imperial Valley, with concrete. The SDCWA will fund the project and receive 77,000
  acre-feet of the water that is conserved.
- Quantify for the first time the total Colorado River allotments for water districts within California.

### Water Portfolios for Water Years 1998, 2000 and 2001

Hydrologic conditions for water years 1998 and 2000 apparently impacted the water supply and water use characteristics for the South Coast Hydrologic Region. In WY 1998, rainfall totals ranged from 170 percent of average in San Diego County to more than 250 percent of average in Ventura County with more than 50 percent of the annual precipitation in January and February. In comparison, during WY 2000 rainfall totals ranged from 60 percent of average in San Diego County to more than 100 percent of average in Ventura County.

In contrast, precipitation amounts for the region for WY 2000 were actually about average to moderately below average. Rainfall deficits increased from north to south.

Storage Changes in the Region [+] Water added to storage [–] Water removed from storage			
Change in Surface Reservoir Storage	372	128	332
Change in Groundwater Storage **	-1,232	-1,527	-1,336
Total	-860	-1,399	-1,004

Applied Water * (compare with Consumptive Use)	4,204	5,052	4,801
* Definition - Consumptive use is the amount of applied water used and no longer available as a source of supply. Applied water is greater than consumptive use because it includes consumptive use, reuse, and outflows.			

Water Entering the Region - Water Leaving the Region = Storage Changes in Region

### \*\*Footnote for change in Groundwater Storage

Change in Groundwater Storage is based upon best available information. Basins in the north part of the State (North Coast, San Francisco, Sacramento River and North Lahontan Regions and parts of Central Coast and San Joaquin River Regions) have been modeled – spring 1997 to spring 1998 for the 1998 water year and spring 1999 to spring 2000 for the 2000 water year. All other regions and year 2001 were calculated using the following equation:

#### GW change in storage =

intentional recharge + deep percolation of applied water + conveyance deep percolation - withdrawals

This equation does not include the unknown factors such as natural recharge and subsurface inflow and outflow.
